

While building my program I came up with a serious issue. I use a computer with linux to write and run code, however my main computer, with which I eventually return code is a MacBook running macOS. For command line programs this was no issue, however running tkinter on the two operating systems produced lots of question marks.

For example running the exact same code (first linux, second macOS) returned the following:

Colors wouldn't show on macOS and the formatting was way off. Even the font of the title appears different, which is weird because I passed in an argument for it. I did a quick tour on google and realized this issue is beyond my reach. Apparently macOS is somehow configured to display tkinter differently compared to other environments, and all advice I found was to use some other GUI library than tkinter.

Anyhow, I came to the conclusion to cut off some complexity, develop my program on linux and upload the final code regardless of what it looks like on macOS. I am not aware of what OS the reviewers are using, so there is really not much for me to do, other than hope for the best. Chances are my code will be run on Windows, so I really have no idea how it will look (I do not own and have never written/ran code on Windows).
